* Args Vs

** Kwargs

Presentation by : Srinil & Rucha

waylonwalker.com/parg

What is *Args?

***An asterisk (*) is used to take in variable arguments with the word args.**

It allows you to take in more arguments than the no. of defined arguments

For example : we want to make a multiply function that takes any number of arguments and able to multiply them all together. It can be done using *args.

Args passes variable number of non-keyworded arguments list and on which operation of the list can be performed.

Examples of *Args

What is **Kwargs?

Double asterisk (**) are used to take in variable keyword arguments with the word `kwargs`.

One can think of the *kwargs* as being a dictionary that maps each keyword to the value that we pass alongside it.

Example of
**Kwargs

*Any
questions?*

*Thank
you*
